Commercial Proposal

QuantBud

Three-week product development milestone following a completed proof of concept.

1. Executive Summary

This proposal defines the next three-week QuantBud product-development milestone at a fixed fee of USD 800. The two-week proof of concept has already produced a working native macOS application for screenshot-grounded trading conversations. This milestone turns that validated foundation into three user-facing capabilities: voice command input, visual candle annotation, and trading-news retrieval.

Commercial position

The two-week PoC was completed without charge and is not being billed retrospectively. The USD 800 price applies only to the next milestone: implementation, integration, testing, and demonstration of the agreed deliverables.

2. Milestone at a Glance

Item	Agreement
Duration	3 weeks (15 weekdays and 6 weekend days)
Fixed milestone fee	USD 800
Estimated effort	Approximately 39-51 hours
Primary outcome	A demonstrable macOS QuantBud build with the three features defined in Section 4
Delivery basis	Agreed acceptance criteria, build verification, and a feature demonstration

Scope principle

The milestone is outcome-focused. Minor implementation decisions that are necessary to meet the acceptance criteria are included. New capabilities, additional data providers, broker integrations, or material design changes outside this document require a separate estimate.

3. Completed Two-Week Proof of Concept

The existing QuantBud codebase is a native macOS proof of concept built with Swift, SwiftUI, AppKit, ScreenCaptureKit, CoreGraphics, SQLite, and the OpenAI Responses API. It is not only a visual mockup: the core capture, analysis, UI, and local-memory workflows are implemented.

Delivered foundation

Area	Existing PoC capability
Companion experience	Click-through floating companion orb; global Command+Shift+Space activation; draggable, responsive answer panel; edge-aware placement across multiple displays.
Visual capture	Screen Recording permission handling; active-window capture with cursor-region fallback; multi-display coordinate mapping; in-memory cursor marker; manual Highlight region selection.
AI analysis	Fresh screenshot per question; OpenAI multimodal Responses API integration; screenshot-grounded trading prompt; bounded follow-up context; visible chart-location response with optional pointer target.
Chart guidance	Validated pointer movement to a model-identified candle, level, or chart feature; automatic Highlight retry when the target is unreliable.
Local product memory	SQLite-backed local conversations, saved insights, preferences, history browser, recent chats, and memory settings. Screenshots are not persisted.
Engineering foundation	Layered Core / Domain / Data / UI architecture, dependency injection, provider abstraction, error states, unit/UI test coverage, configuration and documentation.

Current boundaries

The PoC does not yet include microphone speech input, real on-screen annotations, a live news feed, market-data feeds, broker connections, or automated trading. These boundaries are intentional and inform the next milestone scope.

4. Proposed Feature Scope

Each feature below is scoped to work with the existing screenshot-grounded QuantBud architecture and preserve the app's no-trade-execution boundary.

4.1 Voice command prompt

- Add a microphone-triggered voice input flow to the companion panel, including recording, listening, processing, cancellation, and clear error states.
- Convert spoken English prompts into editable text before the user sends the request, so the current screenshot-analysis workflow remains authoritative.
- Handle microphone and speech-recognition permission states, unavailable recognition, and user cancellation without blocking the existing typed prompt.

4.2 Auto circling, highlighting, and drawing on candles

- Extend the existing model chart-location response from a single pointer target to a constrained annotation plan for relevant visible candles, levels, or chart features.
- Render circles, highlights, arrows, and short labels on a QuantBud-controlled overlay or annotated capture preview, synchronized to the captured chart coordinates.
- Validate coordinates and suppress uncertain annotations; users can retain the current Highlight-region fallback when the chart evidence is unclear.

This feature does not automate TradingView, MetaTrader, a browser, or another third-party charting application. It annotates the captured visual context within QuantBud, avoiding unsupported external UI control.

4.3 Trading news API

- Add a provider boundary and HTTP client integration for one agreed trading-news API, configured through local secrets rather than hard-coded credentials.
- Fetch and present a bounded, source-attributed news list relevant to an agreed symbol, market, or query, with timestamp, loading, empty, and error states.
- Make external news explicit in the analysis flow so QuantBud distinguishes API-sourced facts from visible screenshot evidence and does not invent market causes.

5. Acceptance Criteria and Delivery Plan

The following criteria convert the feature scope into testable outcomes. Exact visual styling and the selected news provider can be finalized during implementation without expanding scope.

Feature	Acceptance criteria
Voice command prompt	User can start and stop voice capture; a successful transcription appears in the editable prompt; the existing Send action submits it; typed input remains available; permission and recognition failures are understandable and recoverable.
Candle annotation	For a supported visible-chart request, QuantBud can show validated circles, highlights, arrows, or labels aligned to identified chart coordinates. Uncertain results show no fabricated mark and preserve the existing region-selection fallback.
Trading news API	With a configured API key and agreed provider, QuantBud can retrieve and display a bounded current-news result with title, source, and timestamp; unavailable or failed requests present a usable state; API data remains clearly separate from screenshot observations.

Three-week delivery focus

Implementation focus	Milestone outcome
Voice-input architecture, permissions, English transcription state, and editable prompt integration; annotation response contract, coordinate validation, overlay/capture rendering, and fallback handling; news provider integration, presentation states, end-to-end testing, hardening, and demonstration preparation.	A voice-to-text prompt works alongside the typed workflow; supported chart annotations render against a captured chart; news results and all three workflows are ready to demonstrate.

Verification

The delivery includes build verification, relevant unit-test updates, and manual acceptance checks for permissions, visual alignment, network failure handling, and the existing capture workflow. Interactive testing will require a locally signed macOS build with Screen Recording permission; microphone and speech-recognition testing will additionally require the relevant macOS permissions.

6. Commercial Offer and Assumptions

Commercial item	Terms
Milestone fee	USD 800 fixed price
Milestone duration	3 weeks
Expected effort	Approximately 39-51 hours
Payment	Payment terms can be discussed further through chat. Payment is due after the agreed deliverables are demonstrated or delivered.
Scope change	Material additions or changes outside Section 4 are estimated and agreed as a new milestone or adjustment before implementation.

Implementation assumptions

- Speech recognition is delivered using macOS-supported capability available to the target OS. A paid third-party transcription service, new backend, or multi-platform client is out of scope unless separately agreed.
- Annotations are limited to information that is visibly and reliably identified in the captured chart. They are visual aids, not trading signals, financial advice, or automation.
- QuantBud remains a local macOS application. Broker connections, order placement, automated trading, live-price feeds, and third-party chart-platform automation are excluded.
